

Detailed meta-analysis on ETS and Lung Cancer

Authors: P.N. Lee and B.A. Forey

16-FEB-04

The output provides full details of a variety of meta-analyses of ETS and lung cancer.

For each table, the output shows, for each individual estimate selected for the meta-analysis, the value of that estimate (RR) and its 95% confidence interval. A study may provide multiple estimates relevant to the exposure being considered in the table. Choice of which to include is governed by an order of preference based on one or more characteristics of the estimate. For example, for Table 1 (spouse or nearest equivalent) data for spousal exposure are chosen if available, otherwise household exposure, and failing that total exposure.

Tables 1-25 give information for spouse ETS exposure (or nearest equivalent) for females (i.e. female subjects, exposure is smoking by the husband)

1. Overall analysis - adjusted
2. " - unadjusted
3. By continent - adjusted
4. " - unadjusted
5. By country within Asia - adjusted
6. By region within Europe - adjusted
7. By publication year (grouped 1) - adjusted
8. " (grouped 2) - adjusted
9. By number of female lung cancer cases (grouped) - adjusted
10. By number of male+female lung cancer cases (grouped) - adjusted
11. By full histological confirmation or not - adjusted
12. By study type (case-control, prospective) - adjusted
13. By study/control type - adjusted
14. By study quality (PNL criteria) - adjusted
15. By numbers of confounders considered (grouped) - adjusted
16. By age considered as confounder or not - adjusted
17. By marital status considered as confounder or not - adjusted
18. By results available on dose-response - adjusted
19. By spouse the index or not - adjusted
20. By end year of study (grouped) - adjusted
21. By considered by EPA or not - adjusted
22. By never smoker definition - adjusted
23. By interview method/setting - adjusted
24. By any proxy use or not - adjusted
25. By proxy use differs markedly in cases and controls or not (CC studies only) - adjusted

Tables 26-29 correspond to Tables 1-4 for spouse ETS exposure (or nearest equivalent) for males, and Tables 30-54 correspond to Tables 1-25 for spouse ETS exposure (or nearest equivalent) for both sexes.

For the remainder of the output, each group of 4 tables corresponds to Tables 1-4.

Tables 55-58 give results for spouse ETS exposure (specifically) for females, Tables 59-62 for spouse ETS exposure (specifically) for males, and Tables 63-66 for spouse ETS exposure (specifically) for both sexes.

The remaining tables are for both sexes. The next tables give results for spouse ETS exposure (or nearest equivalent) for two of the main histological types (or nearest equivalent), with Tables 67-70 for Squamous, and Tables 71-74 for Adenocarcinoma.

Tables 75-78 give information for workplace ETS exposure (using data for workers only if available).

The next tables give information on childhood ETS exposure:

- 79-82. For the most comprehensive index available, choosing mother if no more comprehensive available
- 83-86. For mother specifically
- 87-90. For father specifically
- 91-94. For parents specifically

The next tables give results for household ETS exposure. Since studies vary considerably in how data for this source of ETS is presented (some giving an overall result and others sub-dividing according to the specific source within the household) tables using various different orders of preference are given:

- 95-98. For most comprehensive index available, choosing mother if no more comprehensive available
- 99-102. For most comprehensive index available, choosing father if no more comprehensive available
- 103-106. For mother specifically
- 107-110. For father specifically
- 111-114. Excluding parents and spouse, otherwise most comprehensive index available
- 115-118. Excluding spouse, otherwise most comprehensive index available, choosing mother if no more comprehensive available
- 119-122. Excluding spouse, otherwise most comprehensive index available, choosing father if no more comprehensive available

Tables 123-126 give information on travel ETS exposure, Tables 127-130 give information on social ETS exposure (repeated as Tables 131-134 with study Janerich excluded), and Tables 135-138 give information on total ETS exposure.

The term "relative risk" (RR) is taken to include direct estimates of the relative risks from prospective studies, and indirect estimates (odds ratios) from case-control studies.

"Adjusted" implies that covariate adjusted estimates are chosen if available with unadjusted estimates used otherwise. Where the source publication provides more than one adjusted estimate, the data chosen are those adjusted for most covariates. "Unadjusted" implies that covariate unadjusted estimates are used if available with adjusted estimates used otherwise.

In all tables, estimates originally given for males and females separately are chosen if available in preference to a combined estimate. (In those studies where only a combined sex estimate was originally available for spouse (or nearest equivalent) exposure, then separate sex estimates have been constructed if possible and are used in all sex-specific analyses). In all tables, except those for specific histological types (Tables 67-74) estimates relating to all lung cancer types (or the most comprehensive group available) are used. The other variables used in selecting the estimates, and their values for each estimate chosen, are shown in the output and explained in fuller detail in the footnotes to that table. For each estimate, the table also shows:

StN	The study reference number as used in the database from which the output is produced
Ref	The study 6-letter reference on the database
NRR	The number of the estimate within that study on the database
SEX	The sex of the estimate, m = male, f = female or c = combined
ADJ	The number of adjustment factors (excluding sex) in the estimate

The estimates are shown in blocks according to the "factor" relevant to that table, e.g. continent for Table 3, country for Table 5, etc. Note that these factors relate to the study as a whole, with the exception of sex and spouse the index, which relate to the individual estimates.

For Tables 1, 2, 26, 27, 30, 31, 55, 56, 59, 60 etc, which are not subdivided by factor, a second block of output gives further details regarding each estimate:

Ys	= log RR
Ws	= the weight of the study = 1/(variance Ys)
Q	= the deviation of the study estimate from the mean = Ws (Ys - \bar{Y}) where \bar{Y} is the mean of Ys (this is an approximate chisquared on 1 degree of freedom)
P	= the two-tailed probability value.

For these tables, the output then shows the meta-analysis results, as follows:

N	= number of estimates combined
NS	= number of studies from which estimates taken
Wt	= the sum of the individual estimate weights
Het Chi	= heterogeneity chisquared (between estimates)
Het df	= heterogeneity degrees of freedom
Het P	= heterogeneity probability value, expressed as *** p<0.01; ** p<0.01; * p<0.05; (*) p<0.1; NS p>= 0.1
Fixed RR	= fixed-effect meta-analysis relative risk estimate
RRl, RRu	= the corresponding lower and upper 95% confidence limits
P	= the corresponding probability value, expressed as +++, --- p<0.001; ++, -- P<0.01; +, - p<0.05; (+), (-) p<0.1; NS P>=0.1, with plus signs indicating significant increases and minus signs significant decreases
Random RR	= random-effect meta-analysis relative risk estimated, together with corresponding confidence limits and probability value
AsymmP	= the publication bias probability value based on Egger's test

For the other tables, this information is not only given for all the studies combined, but also by factor level. Additionally results of heterogeneity tests for variation by factor level are shown.

Between Chi	= for the overall data this is the chisquared for heterogeneity, by factor level this is the contribution to the overall chisquared from the data for that level
Between df	= The degrees of freedom for the test of heterogeneity between factor levels
Between P	= Heterogeneity probability value, expressed as for Het P

The methods used for meta-analysis are described in Fleiss and Gross (1991), Journal of Clinical Epidemiology, 44, 127-139. Egger's test is described in Egger et al (1997), BMJ, 315, 629-634. PNL's criteria for study quality are described in Kasuga (ed) Environmental tobacco smoke, Springer-Verlag, New York (1993).

This document is available at www.pnlee.co.uk, download LEE2004E. The results are also summarized in the following documents: download LEE2004.pdf (which includes references to the individual studies), LEE2004B and LEE2004C.

 Within each study, results are included (in the following order of preference) for:
 1) UNX Unexposed = no childhood exposure from specified person (6), no childhood exposure (2)
 Values are also shown for: CHI Childhood exposure = parents (p)
 Where more than one time period within childhood was available, the index relating to the youngest exposure was used
